Package: sspm (via r-universe)

February 13, 2025

```
Type Package
Title Spatial Surplus Production Model Framework for Northern Shrimp
     Populations
Version 1.0.3
Description Implement a GAM-based (Generalized Additive Models)
     spatial surplus production model (spatial SPM), aimed at
     modeling northern shrimp population in Atlantic Canada but
     potentially to any stock in any location. The package is
     opinionated in its implementation of SPMs as it internally
     makes the choice to use penalized spatial gams with time lags.
     However, it also aims to provide options for the user to
     customize their model. The methods are described in Pedersen et
     al. (2022,
     <https://www.dfo-mpo.gc.ca/csas-sccs/Publications/ResDocs-DocRech/2022/2022_</pre>
     062-eng.html>).

```
as\_discretization\_method
```

Cast into a discretization_method object

Description

Cast a character value into discretization_method object, using the list of possible methods in spm_methods.

Usage

```
as_discretization_method(name, method)
## S4 method for signature 'character,ANY'
as_discretization_method(name)
## S4 method for signature 'missing,function'
as_discretization_method(method)
```

Arguments

name [character] The name of the method.

method [character] If custom method, the function to use. See spm_discretize for

more details.

Value

An objectof class discretization_method.

See Also

```
spm_methods.
```

Examples

```
as_discretization_method("tesselate_voronoi")
```

4 catch_simulated

borealis_simulated

Simulated biomass data

Description

Simulated biomass data for test and practice.

Usage

borealis_simulated

Format

A data frame:

year_f Year as a factor
sfa SFA ID number
weight_per_km2 Simualated biomass in kg per km2
temp_at_bottom Simulated water temperature
lon_dec Longitude
lat_dec Latitude
row Row ID
uniqueID Unique ID for simulated observation

catch_simulated

Simulated catch data

Description

Simulated catch data for test and practice.

Usage

catch_simulated

Format

A data frame:

year_f Year as a factor
sfa SFA ID number
catch Simualated catch in kg
lon_dec Longitude
lat_dec Latitude
row Row ID
uniqueID Unique ID for simulated observation

```
discretization_method-class 
 sspm discretization method class
```

Description

This class encapsulates a name and a method (function) used for discretization.

Slots

```
name [character] Name of the discretization method. method [function] Function used for discretization.
```

method_func

Accessing OR replacing discretization_method model elements

Description

All methods described here allow to access the elements of contained in objects of class discretization_method.

Usage

```
method_func(sspm_object)

## S4 method for signature 'discretization_method'
method_func(sspm_object)

method_func(object) <- value

## S4 replacement method for signature 'discretization_method'
method_func(object) <- value

## S4 method for signature 'discretization_method'
spm_name(sspm_object)

## S4 replacement method for signature 'discretization_method'
spm_name(object) <- value</pre>
```

Arguments

```
sspm_object [discretization_method] An object of class discretization_method.
object [discretization_method] An object of class discretization_method.
value typically an array-like R object of a similar class as x.
```

6 plot

Value

The object in the required slot.

Examples

```
method <- as_discretization_method("tesselate_voronoi")
method_func(method)</pre>
```

plot

 $Plot \; {\tt sspm} \; objects$

Description

Plot methods for a range of sspm objects.

```
## S4 method for signature 'sspm_boundary,missing'
plot(x, y, ...)
## S4 method for signature 'sspm_dataset,missing'
plot(
 Х,
 у,
  . . . ,
  var = NULL,
  point_size = 1,
  line_size = 1,
  use_sf = FALSE,
  interval = FALSE,
  page = "first",
 nrow = 2,
 ncol = 2,
 log = FALSE,
  scales = "fixed",
  show_PI = TRUE,
  show_CI = TRUE
)
## S4 method for signature 'sspm_fit,missing'
plot(
 Х,
 у,
  point_size = 1,
  line_size = 1,
  train_test = FALSE,
```

7 plot

```
biomass = NULL,
  next_ts = FALSE,
  smoothed_biomass = FALSE,
  aggregate = FALSE,
  interval = FALSE,
  biomass_origin = NULL,
  use_sf = FALSE,
  page = "first",
  nrow = 2,
  ncol = 2,
  log = FALSE,
  scales = "fixed",
  show_PI = TRUE,
  show_CI = TRUE
)
```

Arguments

Х [sspm_...] An object from this package. y NOT USED (from generic). NOT USED (from generic). [character] (For sspm_dataset) Variable to plot. var point_size [numeric] Passed on to ggplot size parameter for point size. line_size [numeric] Passed on to ggplot size parameter for line size. [logical] Whether to produce a spatial plot. use_sf [logical] (For sspm_fit & sspm_dataset) Whether to plot CI and PI intervals. interval page The page to draw Number of rows per page nrow ncol Number of columns per page log [logical] For productivity, whether to plot log productivity, (default to FALSE) for others, whether to plot on a log scale (default to TRUE). scales Are scales shared across all facets (the default, "fixed"), or do they vary across rows ("free_x"), columns ("free_y"), or both rows and columns ("free")? [character] Whether to show the PIs. show_PI show_CI [character] Whether to show the CIs. [logical] (For sspm_fit) Whether to plot a train/test pair plot. train_test [character] (For sspm_fit) The biomass variable for predictions. biomass [logical] (For sspm_fit) Whether to plot a predictions for next timestep. next_ts smoothed_biomass [logical] (For sspm fit) Whether to plot a the smoothed biomass used for predictions. aggregate

[logical] (For sspm fit) For biomass predictions only, whether to aggregate the

data to the boundary level. Default to FALSE.

biomass_origin [character] Biomass variable to plot (from original dataset, optionnal).

8 predator_simulated

Value

A ggplot2 plot object.

Examples

```
## Not run:
# To plot a boundary object and visualize patches/points
plot(sspm_boundary)
# To plot a dataset variable
plot(biomass_smooth, var = "weight_per_km2", log = FALSE)
plot(biomass_smooth, var = "weight_per_km2", use_sf = TRUE)
# To plot a fitted model
# Test-train plot
plot(sspm_model_fit, train_test = TRUE, scales = "free")
# Timeseries plot
plot(sspm_model_fit, log = T, scales = 'free')
plot(sspm_model_fit, log = T, use_sf = TRUE)
plot(sspm_model_fit, biomass = "weight_per_km2_borealis", scales = "free")
plot(sspm_model_fit, biomass = "weight_per_km2_borealis", use_sf = TRUE)
plot(sspm_model_fit, biomass = "weight_per_km2_borealis",
     next_ts = TRUE, aggregate = TRUE, scales = "free", interval = T)
## End(Not run)
```

predator_simulated

Simulated predator data

Description

Simulated predator data for test and practice.

Usage

```
predator_simulated
```

Format

```
A data frame:

year_f Year as a factor

sfa SFA ID number

weight_per_km2 Simualated biomass in kg per km2

lon_dec Longitude

lat_dec Latitude

row Row ID

uniqueID Unique ID for simulated observation
```

predict 9

predict

Predict with a SPM model

Description

Predict using a fitted SPM model on the whole data or on new data

Usage

```
## S4 method for signature 'sspm_fit'
predict(
  object,
  new_data = NULL,
  biomass = NULL,
  aggregate = FALSE,
  interval = FALSE,
  next_ts = FALSE,
  type = "response"
)
## S4 method for signature 'sspm_dataset'
predict(
  object,
  new_data = NULL,
  discrete = TRUE,
  type = "response",
  interval = FALSE
)
```

Arguments

object	[sspm_fit] Fit object to predict from.
new_data	[data.frame] New data to predict with.
biomass	[character] Biomass variable.
aggregate	[logical] For biomass predictions only, whether to aggregate the data to the boundary level. Default to FALSE.
interval	[logical] Whether or not to calculate confidence, and when possible, prediction intervals.
next_ts	[logical] For biomass, predict next timestep.
type	When this has the value "link" (default) the linear predictor (possibly with associated standard errors) is returned. When type="terms" each component of the linear predictor is returned seperately (possibly with standard errors): this includes parametric model components, followed by each smooth component,

but excludes any offset and any intercept. type="iterms" is the same, except

10 predict_intervals

that any standard errors returned for smooth components will include the uncertainty about the intercept/overall mean. When type="response" predictions on the scale of the response are returned (possibly with approximate standard errors). When type="lpmatrix" then a matrix is returned which yields the values of the linear predictor (minus any offset) when postmultiplied by the parameter vector (in this case se.fit is ignored). The latter option is most useful for getting variance estimates for quantities derived from the model: for example integrated quantities, or derivatives of smooths. A linear predictor matrix can also be used to implement approximate prediction outside R (see example code, below).

discrete

[logical] If new_data is NULL, whether to predict based on a discrete prediction matrix (default to TRUE).

Value

A dataframe of predictions.

Examples

```
## Not run:
# Predictions for a model fit (usually, productivity)
predict(sspm_model_fit)
# To get biomass predictions, provide the variable name
predict(sspm_model_fit, biomass = "weight_per_km2_borealis")
# To get the next timestep predictions
predict(sspm_model_fit, biomass = "weight_per_km2_borealis", next_ts = TRUE)
## End(Not run)
```

predict_intervals

GAM confidence and prediction intervals

Description

Computes CI from posterior, and PI for Tweedie and scat gams.

Usage

```
predict_intervals(object_fit, new_data, n = 1000, CI = TRUE, PI = TRUE, ...)
```

Arguments

object_fit	[gam OR bam] The fit to use for predictions.
new_data	[data.frame] The data to predict onto.
n	[numeric] The number of simulations to run for parameters.
CI	[logical] Whether to compute the CI.
PI	[logical] Whether to compute the PI.
	further arguments passed to the quantile function.

raw_formula 11

Value

A data. frame with intervals.

Examples

```
gam1 <- gam(cyl ~ mpg, data=mtcars, family = tw)
predict_intervals(gam1)</pre>
```

raw_formula

Accessing OR replacing sspm_formula model elements

Description

All methods described here allow to access the elements of contained in objects of class sspm_formula.

```
raw_formula(sspm_object)
## S4 method for signature 'sspm_formula'
raw_formula(sspm_object)
raw_formula(object) <- value</pre>
## S4 replacement method for signature 'sspm_formula'
raw_formula(object) <- value</pre>
translated_formula(sspm_object)
## S4 method for signature 'sspm_formula'
translated_formula(sspm_object)
translated_formula(object) <- value</pre>
## S4 replacement method for signature 'sspm_formula'
translated_formula(object) <- value</pre>
formula_vars(sspm_object)
## S4 method for signature 'sspm_formula'
formula_vars(sspm_object)
formula_vars(object) <- value</pre>
## S4 replacement method for signature 'sspm_formula'
formula_vars(object) <- value</pre>
```

12 raw_formula

```
formula_type(sspm_object)
## S4 method for signature 'sspm_formula'
formula_type(sspm_object)
formula_type(object) <- value</pre>
## S4 replacement method for signature 'sspm_formula'
formula_type(object) <- value</pre>
is_fitted(sspm_object)
## S4 method for signature 'sspm_formula'
is_fitted(sspm_object)
is_fitted(object) <- value</pre>
## S4 replacement method for signature 'sspm_formula'
is_fitted(object) <- value</pre>
spm_response(sspm_object)
## S4 method for signature 'sspm_formula'
spm_response(sspm_object)
spm_response(object) <- value</pre>
## S4 replacement method for signature 'sspm_formula'
spm_response(object) <- value</pre>
spm_lagged_vars(sspm_object)
## S4 method for signature 'sspm_formula'
spm_lagged_vars(sspm_object)
spm_lagged_vars(object) <- value</pre>
## S4 replacement method for signature 'sspm_formula'
spm_lagged_vars(object) <- value</pre>
```

Arguments

sspm_object	[sspm_formula] An object of class sspm_formula.
object	[sspm_formula] An object of class sspm_formula.
value	typically an array-like R object of a similar class as x.

sfa_boundaries 13

Value

The object in the required slot.

Examples

sfa_boundaries

SFA boundaries data

Description

SFA boundaries.

Usage

sfa_boundaries

Format

A data frame and sf object:

```
sfa SFA ID numbergeometry sf geometryarea sf geometry area
```

Source

https://www.dfo-mpo.gc.ca/fisheries-peches/ifmp-gmp/shrimp-crevette/shrimp-crevette-2018-002-eng.html

smooth_time

 $smooth_time$

sspm Smoothing functions

Description

A full sspm formula contains calls to the smoothing terms smooth_time(), smooth_space(), smooth_space_time().

```
smooth_time(
  data_frame,
  boundaries,
  time,
  type = "ICAR",
  k = NULL,
 bs = "re",
 xt = NA,
  is_spm = FALSE,
)
smooth_space(
  data_frame,
  boundaries,
  time,
  type = "ICAR",
  k = NULL,
 bs = "mrf",
  xt = NULL,
  is_spm = FALSE,
)
smooth_space_time(
  data_frame,
  boundaries,
  time,
  type = "ICAR",
  k = c(NA, 30),
 bs = c("re", "mrf"),
xt = list(NA, NULL),
  is_spm = FALSE,
)
smooth_lag(
```

smooth_time 15

```
var,
  data_frame,
 boundaries,
  time,
  type = "LINPRED",
 k = 5,
 m = 1,
)
## S4 method for signature 'sf,sspm_discrete_boundary'
smooth_time(
  data_frame,
 boundaries,
  time,
  type = "ICAR",
  k = NULL,
 bs = "re",
 xt = NA,
  is_spm = FALSE,
)
## S4 method for signature 'sf,sspm_discrete_boundary'
smooth_space(
  data_frame,
 boundaries,
  time,
  type = "ICAR",
  k = NULL,
 bs = "mrf",
 xt = NULL,
  is_spm = FALSE,
)
## S4 method for signature 'sf,sspm_discrete_boundary'
smooth_space_time(
  data_frame,
 boundaries,
  time,
  type = "ICAR",
 k = c(NA, 30),
 bs = c("re", "mrf"),
 xt = list(NA, NULL),
  is_spm = FALSE,
)
```

smooth_time

```
## S4 method for signature 'ANY,sf,sspm_discrete_boundary'
smooth_lag(
  var,
  data_frame,
  boundaries,
  time,
  type = "LINPRED",
  k = 5,
  m = 1,
  ...
)
```

Arguments

data_frame	[sf data.frame] The data.
boundaries	[sspm_boundary] An object of class sspm_discrete_boundary.
time	[character] The time column.
type	[character] Type of smooth, currently only "ICAR" is supported.
k	[numeric] Size of the smooths and/or size of the lag.
bs	a two letter character string indicating the (penalized) smoothing basis to use. (eg "tp" for thin plate regression spline, "cr" for cubic regression spline). see smooth.terms for an over view of what is available.
xt	Any extra information required to set up a particular basis. Used e.g. to set large data set handling behaviour for "tp" basis. If xt\$sumConv exists and is FALSE then the summation convention for matrix arguments is turned off.
is_spm	Whether or not an SPM is being fitted (used internally)
	a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. $s(log(x))$ is fine, but $s(I(x/sd(x)))$ is not (see predict.gam).
var	[symbol] Variable (only for smooth_lag).
m	The order of the penalty for this term (e.g. 2 for normal cubic spline penalty with 2nd derivatives when using default t.p.r.s basis). NA signals autoinitialization. Only some smooth classes use this. The "ps" class can use a 2 item array giving the basis and penalty order separately.

Value

A list of 2 lists:

- args, contains the arguments to be passed on to the mgcv smooths
- vars, contains variables relevant to the evaluation of the smooth.

spm 17

Examples

```
## Not run:
# Not meant to be used directly
smooth_time(borealis_data, bounds_voronoi, time = "year")
## End(Not run)
```

spm

Fit an SPM model

Description

Fit an spm model to a sspm object

Usage

```
spm(sspm_object, formula, ...)
## S4 method for signature 'sspm,missing'
spm(sspm_object, formula, ...)
## S4 method for signature 'sspm,formula'
spm(sspm_object, formula, ...)
```

Arguments

sspm_object [sspm_dataset] An object of class sspm_dataset.

formula [formula] A formula definition of the form response ~ smoothing_terms + ...

Arguments passed on to mgcv::bam

family This is a family object specifying the distribution and link to use in fitting etc. See glm and family for more details. The extended families listed in family.mgcv can also be used.

- data A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from environment(formula): typically the environment from which gam is called.
- weights prior weights on the contribution of the data to the log likelihood. Note that a weight of 2, for example, is equivalent to having made exactly the same observation twice. If you want to reweight the contributions of each datum without changing the overall magnitude of the log likelihood, then you should normalize the weights (e.g. weights <- weights/mean(weights)).
- subset an optional vector specifying a subset of observations to be used in the fitting process.
- na.action a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.

18 spm

offset Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in formula (this used to conform to the behaviour of lm and glm).

- method The smoothing parameter estimation method. "GCV.Cp" to use GCV for unknown scale parameter and Mallows' Cp/UBRE/AIC for known scale. "GACV.Cp" is equivalent, but using GACV in place of GCV. "REML" for REML estimation, including of unknown scale, "P-REML" for REML estimation, but using a Pearson estimate of the scale. "ML" and "P-ML" are similar, but using maximum likelihood in place of REML. Default "fREML" uses fast REML computation.
- control A list of fit control parameters to replace defaults returned by gam. control. Any control parameters not supplied stay at their default values.
- select Should selection penalties be added to the smooth effects, so that they can in principle be penalized out of the model? See gamma to increase penalization. Has the side effect that smooths no longer have a fixed effect component (improper prior from a Bayesian perspective) allowing REML comparison of models with the same fixed effect structure.
- scale If this is positive then it is taken as the known scale parameter. Negative signals that the scale paraemter is unknown. 0 signals that the scale parameter is 1 for Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.
- gamma Increase above 1 to force smoother fits. gamma is used to multiply the effective degrees of freedom in the GCV/UBRE/AIC score (so log(n)/2 is BIC like). n/gamma can be viewed as an effective sample size, which allows it to play a similar role for RE/ML smoothing parameter estimation.
- knots this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the k value supplied (note that the number of knots is not always just k). See tprs for what happens in the "tp"/"ts" case. Different terms can use different numbers of knots, unless they share a covariate.
- sp A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then length(sp) must correspond to the number of underlying smoothing parameters. Note that discrete=TRUEmay result in re-ordering of variables in tensor product smooths for improved efficiency, and sp must be supplied in re-ordered order.
- min.sp Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters full.sp, in the returned object, will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. length(min.sp) should always be the same as the total number of penalties (so it may be longer than sp, if smooths share smoothing parameters).

spm 19

paraPen optional list specifying any penalties to be applied to parametric model terms. gam.models explains more.

- chunk.size The model matrix is created in chunks of this size, rather than ever being formed whole. Reset to 4*p if chunk.size < 4*p where p is the number of coefficients.
- rho An AR1 error model can be used for the residuals (based on dataframe order), of Gaussian-identity link models. This is the AR1 correlation parameter. Standardized residuals (approximately uncorrelated under correct model) returned in std.rsd if non zero. Also usable with other models when discrete=TRUE, in which case the AR model is applied to the working residuals and corresponds to a GEE approximation.
- AR. start logical variable of same length as data, TRUE at first observation of an independent section of AR1 correlation. Very first observation in data frame does not need this. If NULL then there are no breaks in AR1 correlation.
- discrete with method="fREML" it is possible to discretize covariates for storage and efficiency reasons. If discrete is TRUE, a number or a vector of numbers for each smoother term, then discretization happens. If numbers are supplied they give the number of discretization bins. Parametric terms use the maximum number specified.
- cluster bam can compute the computationally dominant QR decomposition in parallel using parLapply from the parallel package, if it is supplied with a cluster on which to do this (a cluster here can be some cores of a single machine). See details and example code.
- nthreads Number of threads to use for non-cluster computation (e.g. combining results from cluster nodes). If NA set to max(1,length(cluster)). See details.
- gc.level to keep the memory footprint down, it can help to call the garbage collector often, but this takes a substatial amount of time. Setting this to zero means that garbage collection only happens when R decides it should. Setting to 2 gives frequent garbage collection. 1 is in between. Not as much of a problem as it used to be, but can really matter for very large datasets.
- use.chol By default bam uses a very stable QR update approach to obtaining the QR decomposition of the model matrix. For well conditioned models an alternative accumulates the crossproduct of the model matrix and then finds its Choleski decomposition, at the end. This is somewhat more efficient, computationally.
- samfrac For very large sample size Generalized additive models the number of iterations needed for the model fit can be reduced by first fitting a model to a random sample of the data, and using the results to supply starting values. This initial fit is run with sloppy convergence tolerances, so is typically very low cost. samfrac is the sampling fraction to use. 0.1 is often reasonable.
- coef initial values for model coefficients
- drop.unused.levels by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.
- G if not NULL then this should be the object returned by a previous call to bam with fit=FALSE. Causes all other arguments to be ignored except sp,

20 spm_aggregate

chunk.size, gamma,nthreads, cluster, rho, gc.level, samfrac, use.chol, method and scale (if >0).

fit if FALSE then the model is set up for fitting but not estimated, and an object is returned, suitable for passing as the G argument to bam.

drop.intercept Set to TRUE to force the model to really not have the a constant in the parametric model part, even with factor variables present.

in out If supplied then this is a two item list of intial values. sp is initial smoothing parameter estiamtes and scale the initial scale parameter estimate (set to 1 if family does not have one).

Value

An object of type sspm_fit.

Examples

```
## Not run:
sspm_model_fit <- sspm_model %>%
    spm(log_productivity ~ sfa +
    weight_per_km2_all_predators_lag_1 +
    smooth_space(by = weight_per_km2_borealis_with_catch) +
    smooth_space(),
    family = mgcv::scat)
## End(Not run)
```

spm_aggregate

Aggregate a dataset or fit data variable based on a boundary

Description

Aggregate the data contained in a dataset or fit based on the discretized boundaries, using a function and a filling value.

```
spm_aggregate(
    sspm_object,
    boundaries,
    level = "patch",
    type = "data",
    variable,
    fun,
    group_by = "spacetime",
    fill = FALSE,
    apply_to_df = FALSE,
```

spm_aggregate 21

```
## S4 method for signature 'sspm_dataset,missing'
spm_aggregate(
  sspm_object,
 boundaries,
 level = "patch",
  type = "data",
  variable,
  fun,
 group_by = "spacetime",
 fill = FALSE,
  apply_to_df = FALSE,
)
## S4 method for signature 'sspm_dataset,sspm_discrete_boundary'
spm_aggregate(
  sspm_object,
 boundaries,
 level = "patch",
  type = "data",
  variable,
  fun,
  group_by = "spacetime",
 fill = FALSE,
  apply_to_df = FALSE,
)
```

Arguments

sspm_object	[sspm_dataset or sspm_fit] The dataset object.
boundaries	[sspm_discrete_boundary] The boundaries object (optionnal).
level	[character] The aggregation level, "patch" or "boundary".
type	[character] The targeted type of aggregation, one of "data" for base data or "smoothed" for smoothed data.
variable	[character] Variable to aggregate (ignored in case apply_to_df is TRUE).
fun	[function] Function to use to aggregate data.
group_by	[character] One of time, space and spacetime.
fill	[logical OR numeric OR function] Whether to complete the incomplete cases, default to FALSE for no completion.
apply_to_df	[logical] Wether fun applied to the data frame group or to variable, default to FALSE.
	More arguments passed onto fun

22 spm_aggregate_catch

Value

Updated sspm_dataset or sspm_fit.

Examples

spm_aggregate_catch

Update biomass value from catch adta

Description

Aggregate the catch data contained in a catch dataset and update the biomass dataset with the subtracted catch.

```
spm_aggregate_catch(
 biomass,
  catch,
 biomass_variable,
  catch_variable,
  corrections = NULL,
  fun = sum,
  group_by = "spacetime",
 fill,
 apply_to_df = FALSE,
)
## S4 method for signature 'sspm_dataset,sspm_dataset,character,character'
spm_aggregate_catch(
 biomass,
  catch,
 biomass_variable,
 catch_variable,
  corrections = NULL,
  fun = sum,
```

spm_as_boundary 23

```
group_by = "spacetime",
fill,
apply_to_df = FALSE,
...
)
```

Arguments

biomass [sspm_dataset (smoothed)] The dataset containing the biomass variable.

catch [sspm_dataset] The dataset containing the catch variable.

biomass_variable [character] The biomass variab of biomass.

catch_variable [character] The catch column of catch.

corrections [data.frame] Optional landings corrections.

fun [function] Function to use to aggregate data.

group_by [character] One of time, space and spacetime.

fill [logical OR numeric OR function] Whether to complete the incomplete cases,

default to FALSE for no completion.

apply_to_df [logical] Wether fun applied to the data frame group or to variable, default to

FALSE.

... More arguments passed onto fun

Value

 $Updated \ sspm_dataset.$

Examples

spm_as_boundary

Create a sspm_boundary object

Description

Create a sspm_boundary object. A boundary object serves as a basis to encode the spatial extent of the model.

24 spm_as_boundary

```
spm_as_boundary(
 boundaries,
  boundary,
 patches = NULL,
 points = NULL,
 boundary_area = NULL,
 patch\_area = NULL
)
## S4 method for signature 'missing, ANY, ANY, ANY'
spm_as_boundary(
 boundaries,
 boundary,
 patches = NULL,
 points = NULL,
 boundary_area = NULL,
  patch_area = NULL
)
## S4 method for signature 'ANY, missing, ANY, ANY'
spm_as_boundary(
 boundaries,
 boundary,
 patches = NULL,
  points = NULL,
 boundary_area = NULL,
 patch_area = NULL
)
## S4 method for signature 'sf,character,missing,missing'
spm_as_boundary(
 boundaries,
 boundary,
 patches = NULL,
 points = NULL,
 boundary_area = NULL,
 patch_area = NULL
)
## S4 method for signature 'sf,character,ANY,ANY'
spm_as_boundary(
 boundaries,
 boundary,
 patches = NULL,
 points = NULL,
  boundary_area = NULL,
  patch_area = NULL
```

spm_as_dataset 25

)

Arguments

boundaries [sf] The sf object to cast.

boundary [character] The column that contains the possible subdivisions of the bound-

aries.

patches [sf] Patches resulting from discretization.
points [sf] Sample points used for discretization.

boundary_area [character] The column that contains the area of the subdivisions (optional).

patch_area [character] The column that contains the area of the patches (optional).

Value

An object of class sspm_boundary or sspm_discrete_boundary.

Examples

spm_as_dataset

Create a sspm_dataset dataset structure

Description

This casts a data.frame or sf object into an object of class sspm_dataset. This object is the format the package uses to manage and manipulate the modeling data.

```
spm_as_dataset(data, name, time, uniqueID, coords = NULL, ...)
## S4 method for signature 'data.frame, ANY, ANY, ANY, missingOrNULL'
spm_as_dataset(
    data,
    name,
    time,
    uniqueID,
    coords,
    crs = NULL,
    boundaries = NULL,
    biomass = NULL,
```

26 spm_as_dataset

```
density = NULL,
 biomass_units = NULL,
  density\_units = NULL
)
## S4 method for signature 'data.frame, ANY, ANY, ANY, list'
spm_as_dataset(
 data,
 name,
  time,
 uniqueID,
  coords,
  crs = NULL,
 boundaries = NULL,
 biomass = NULL,
  density = NULL,
 biomass_units = "kg",
  density_units = "kg/km^2"
)
## S4 method for signature 'data.frame, ANY, ANY, ANY, character'
spm_as_dataset(
 data,
 name,
  time,
 uniqueID,
  coords,
  crs = NULL,
 boundaries = NULL,
 biomass = NULL,
  density = NULL,
 biomass_units = "kg",
  density_units = "kg/km^2"
)
## S4 method for signature 'sf,ANY,ANY,ANY,ANY'
spm_as_dataset(
 data,
 name,
 time,
 uniqueID,
  coords,
  crs = NULL,
 boundaries = NULL,
 biomass = NULL,
  density = NULL,
  biomass_units = "kg",
  density_units = "kg/km^2"
```

)

Arguments

data	[data.frame OR sf] The dataset.
name	[character] The name of the dataset, default to "Biomass".
time	[character] The column of data for the temporal dimensions (i.e. year).
uniqueID	[character] The column of data that is unique for all rows of the data matrix.
coords	[character] The column of data for longitude and latitude of the observations.
	Arguments passed onto methods.
crs	Coordinate reference system, passed onto st_as_sf.
boundaries	[sspm_boundary] An object of class sspm_discrete_boundary.
biomass	[character] Columns to be encoded as biomasses (required).
density	[character] Columns to be encoded as densities (optionnal).
biomass_units	[character] Units for biomass columns, default to "kg".
density_units	[character] Units for density columns, default to "kg/km^2".

Value

An object of class sspm_dataset.

Examples

```
{\tt spm\_boundaries,sspm\_boundary-method}
```

Accessing OR replacing sspm_boundary model elements

Description

All methods described here allow to access the elements of contained in objects of class sspm_boundary.

Arguments

```
sspm_object [sspm_dataset] An object of class sspm_dataset.

object [sspm_dataset] An object of class sspm_dataset.

value typically an array-like R object of a similar class as x.
```

Value

The object in the required slot.

Examples

spm_discretize

Discretize a sspm model object

Description

Discretize a sspm model object with a function from a discretization_method object class. This function divides the boundary polygons into smaller patches.

spm_discretize 33

Usage

```
spm_discretize(boundary_object, method = "tesselate_voronoi", with = NULL, ...)
## S4 method for signature 'sspm_boundary,missing,ANY'
spm_discretize(boundary_object, method = "tesselate_voronoi", with = NULL, ...)
## S4 method for signature 'sspm_boundary, ANY, missing'
spm_discretize(boundary_object, method = "tesselate_voronoi", with = NULL, ...)
## S4 method for signature 'sspm_boundary,character,ANY'
spm_discretize(boundary_object, method = "tesselate_voronoi", with = NULL, ...)
## S4 method for signature 'sspm_boundary, function, ANY'
spm_discretize(boundary_object, method = "tesselate_voronoi", with = NULL, ...)
## S4 method for signature 'sspm_boundary,discretization_method,ANY'
spm_discretize(boundary_object, method = "tesselate_voronoi", with = NULL, ...)
```

Arguments

boundary_object

[sspm] An object of class sspm_boundary.

[character OR method] Either a character from the list of available methods method (see spm_methods for the list) **OR** an object of class discretization_method.

with [sspm_dataset OR sf] Either an object of class sspm_dataset or a set of custom

points.

[named list] Further arguments to be passed onto the function used in method. . . .

Details

Custom discretization functions can be written. The function must:

- 1. Accept at least 1 argument: boundaries (the sf boundary object), and optionnaly with (can be NULL) a separate object to be used for discretization and **boundary**, the boundary column of **boundaries** (these last 2 arguments are passed and connot be overwritten but could be ignored).
- 2. Returns a named list with 2 elements: patches. an sf object that stores the discretized polygons, and points, an sf object that stores the points that were used for discretization.

Value

An object of class sspm_discrete_boundary (the updated and discretized sspm object given as input).

Examples

```
# Voronoi tesselation
sfa_boundaries
bounds <- spm_as_boundary(boundaries = sfa_boundaries,</pre>
```

spm_lag

```
boundary = "sfa")
biomass_dataset <- spm_as_dataset(data.frame(borealis_simulated), name = "borealis",</pre>
                                   density = "weight_per_km2",
                                   time = "year_f",
                                   coords = c('lon_dec','lat_dec'),
                                   uniqueID = "uniqueID")
bounds_voronoi <- bounds %>%
 spm_discretize(method = "tesselate_voronoi",
                 with = biomass_dataset,
                 nb\_samples = 10)
# Custom method
custom_func <- function(boundaries, ...){</pre>
 args <- list(...)</pre>
 # Can access passed arguments with args$arg_name
 # Do your custom discretization
 # Careful: must return sf objects!
 return(list(patches = c(),
              points = c())
}
```

spm_lag

Create lagged columns in a sspm smoothed data slot

Description

This function is a wrapper around lag (note that not all arguments are supported). The default value for the lag is the mean of the series.

Usage

```
spm_lag(sspm_object, vars, n = 1, default = "mean", ...)
## S4 method for signature 'sspm'
spm_lag(sspm_object, vars, n = 1, default = "mean", ...)
## S4 method for signature 'sspm_fit'
spm_lag(sspm_object, vars, n = 1, default = "mean", ...)
```

Arguments

sspm_object [sspm_dataset] An object of class sspm_dataset.

vars [character] Names of the variables to lag.

Positive integer of length 1, giving the number of positions to lag or lead by

The value used to pad x back to its original size after the lag or lead has been applied. The default, NULL, pads with a missing value. If supplied, this must be a vector with size 1, which will be cast to the type of x.

spm_methods 35

• • •

a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. $s(\log(x))$ is fine, but s(I(x/sd(x))) is not (see predict.gam).

Value

Updated sspm_object.

Examples

spm_methods

Get the list of available discretization methods

Description

Currently, only one discretization method is supported: * "tesselate_voronoi" Voronoi tessellation using the function tesselate_voronoi.

Usage

```
spm_methods()
```

Details

You can create your own method (tutorial TBD).

Value

A character vector of all available discretization methods.

36 spm_name

spm_name

Accessing OR replacing sspm model elements

Description

All methods described here allow to access the elements of contained in objects of the different classes of the package.

```
spm_name(sspm_object)
spm_name(object) <- value</pre>

is_split(object) <- value</pre>
spm_unique_ID(sspm_object)
## S4 method for signature 'sspm'
spm_unique_ID(sspm_object)
spm_unique_ID(object) <- value</pre>
## S4 replacement method for signature 'sspm'
spm_unique_ID(object) <- value</pre>
```

Arguments

sspm_object [sspm OR adjacent] An object of class sspm or others derivative classes.

object [sspm OR adjacent] An object of class sspm or others derivative classes.

value typically an array-like R object of a similar class as x.

Value

The object in the required slot.

Examples

spm_smooth

Smooth a variable in a sspm dataset

Description

With a formula, smooth a variable in a sspm dataset. See Details for more explanations.

Usage

```
spm_smooth(
   sspm_object,
   formula,
   boundaries,
   keep_fit = TRUE,
   predict = TRUE,
   ...
)

## S4 method for signature 'sspm_dataset,formula,sspm_discrete_boundary'
spm_smooth(
   sspm_object,
   formula,
   boundaries,
   keep_fit = TRUE,
   predict = TRUE,
   ...
)
```

Arguments

sspm_object	[sspm_dataset] An object of class sspm_dataset.
formula	[formula] A formula definition of the form response ~ smoothing_terms +
boundaries	[sspm_boundary] An object of class sspm_discrete_boundary.
keep_fit	[logical] Whether or not to keep the fitted values and model (default to TRUE, set to FALSE to reduce memory footprint).
predict	[logical] Whether or not to generate the smoothed predictions (necessary to fit the final SPM model, default to TRUE).
	Arguments passed on to mgcv::bam
	family This is a family object specifying the distribution and link to use in fitting etc. See glm and family for more details. The extended families listed in family.mgcv can also be used.
	data A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from environment(formula):

typically the environment from which gam is called.

weights prior weights on the contribution of the data to the log likelihood. Note that a weight of 2, for example, is equivalent to having made exactly the same observation twice. If you want to reweight the contributions of each datum without changing the overall magnitude of the log likelihood, then you should normalize the weights (e.g. weights <- weights/mean(weights)).

- subset an optional vector specifying a subset of observations to be used in the fitting process.
- na.action a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.
- offset Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in formula (this used to conform to the behaviour of lm and glm).
- method The smoothing parameter estimation method. "GCV.Cp" to use GCV for unknown scale parameter and Mallows' Cp/UBRE/AIC for known scale. "GACV.Cp" is equivalent, but using GACV in place of GCV. "REML" for REML estimation, including of unknown scale, "P-REML" for REML estimation, but using a Pearson estimate of the scale. "ML" and "P-ML" are similar, but using maximum likelihood in place of REML. Default "fREML" uses fast REML computation.
- control A list of fit control parameters to replace defaults returned by gam.control. Any control parameters not supplied stay at their default values.
- select Should selection penalties be added to the smooth effects, so that they can in principle be penalized out of the model? See gamma to increase penalization. Has the side effect that smooths no longer have a fixed effect component (improper prior from a Bayesian perspective) allowing REML comparison of models with the same fixed effect structure.
- scale If this is positive then it is taken as the known scale parameter. Negative signals that the scale paraemter is unknown. 0 signals that the scale parameter is 1 for Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.
- gamma Increase above 1 to force smoother fits. gamma is used to multiply the effective degrees of freedom in the GCV/UBRE/AIC score (so log(n)/2 is BIC like). n/gamma can be viewed as an effective sample size, which allows it to play a similar role for RE/ML smoothing parameter estimation.
- knots this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the k value supplied (note that the number of knots is not always just k). See tprs for what happens in the "tp"/"ts" case. Different terms can use different numbers of knots, unless they share a covariate.
- sp A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then length(sp) must

- correspond to the number of underlying smoothing parameters. Note that discrete=TRUEmay result in re-ordering of variables in tensor product smooths for improved efficiency, and sp must be supplied in re-ordered order.
- min.sp Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters full.sp, in the returned object, will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. length(min.sp) should always be the same as the total number of penalties (so it may be longer than sp, if smooths share smoothing parameters).
- paraPen optional list specifying any penalties to be applied to parametric model terms. gam.models explains more.
- chunk.size The model matrix is created in chunks of this size, rather than ever being formed whole. Reset to 4*p if chunk.size < 4*p where p is the number of coefficients.
- rho An AR1 error model can be used for the residuals (based on dataframe order), of Gaussian-identity link models. This is the AR1 correlation parameter. Standardized residuals (approximately uncorrelated under correct model) returned in std.rsd if non zero. Also usable with other models when discrete=TRUE, in which case the AR model is applied to the working residuals and corresponds to a GEE approximation.
- AR. start logical variable of same length as data, TRUE at first observation of an independent section of AR1 correlation. Very first observation in data frame does not need this. If NULL then there are no breaks in AR1 correlation.
- discrete with method="fREML" it is possible to discretize covariates for storage and efficiency reasons. If discrete is TRUE, a number or a vector of numbers for each smoother term, then discretization happens. If numbers are supplied they give the number of discretization bins. Parametric terms use the maximum number specified.
- cluster bam can compute the computationally dominant QR decomposition in parallel using parLapply from the parallel package, if it is supplied with a cluster on which to do this (a cluster here can be some cores of a single machine). See details and example code.
- nthreads Number of threads to use for non-cluster computation (e.g. combining results from cluster nodes). If NA set to max(1,length(cluster)). See details.
- gc.level to keep the memory footprint down, it can help to call the garbage collector often, but this takes a substatial amount of time. Setting this to zero means that garbage collection only happens when R decides it should. Setting to 2 gives frequent garbage collection. 1 is in between. Not as much of a problem as it used to be, but can really matter for very large datasets.
- use.chol By default bam uses a very stable QR update approach to obtaining the QR decomposition of the model matrix. For well conditioned models an alternative accumulates the crossproduct of the model matrix and then finds its Choleski decomposition, at the end. This is somewhat more efficient, computationally.
- samfrac For very large sample size Generalized additive models the number of

iterations needed for the model fit can be reduced by first fitting a model to a random sample of the data, and using the results to supply starting values. This initial fit is run with sloppy convergence tolerances, so is typically very low cost. samfrac is the sampling fraction to use. 0.1 is often reasonable.

coef initial values for model coefficients

- drop.unused.levels by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.
- G if not NULL then this should be the object returned by a previous call to bam with fit=FALSE. Causes all other arguments to be ignored except sp, chunk.size, gamma,nthreads, cluster, rho, gc.level, samfrac, use.chol, method and scale (if >0).
- fit if FALSE then the model is set up for fitting but not estimated, and an object is returned, suitable for passing as the G argument to bam.
- drop.intercept Set to TRUE to force the model to really not have the a constant in the parametric model part, even with factor variables present.
- in.out If supplied then this is a two item list of intial values. sp is initial smoothing parameter estiamtes and scale the initial scale parameter estimate (set to 1 if family does not have one).

Details

This functions allows to specify a model formula for a given discrete sspm object. The formula makes use of specific smoothing terms smooth_time(), smooth_space(), smooth_space_time(). The formula can also contain fixed effects and custom smooths, and can make use of specific smoothing terms smooth_time(), smooth_space(), smooth_space_time().

Value

An updated sspm_dataset.

Examples

spm_split

spm_smooth_methods

Get the list of available smoothing methods

Description

Currently, only one smoothing method is supported: * "ICAR": Intrinsic Conditional Auto-Regressive models. * "LINPRED": LINear PREDictors (lag smooths).

Usage

```
spm_smooth_methods()
```

Value

A character vector of all available smoothing methods.

spm_split

Split data in test and train sets

Description

Split data before fitting spm.

Usage

```
spm_split(sspm_object, ...)
## S4 method for signature 'sspm'
spm_split(sspm_object, ...)
```

Arguments

```
sspm_object [sspm] An object of class sspm.
... [expression] Expression to evaluate to split data.
```

Value

The updated sspm object.

Examples

```
## Not run:
sspm_model <- sspm_model %>%
    spm_split(year_f %in% c(1990:2017))
## End(Not run)
```

Description

All methods described here allow to access the elements of contained in objects of class sspm_fit.

Usage

```
## S4 method for signature 'sspm_fit'
spm_unique_ID(sspm_object)
## S4 replacement method for signature 'sspm_fit'
spm_unique_ID(object) <- value</pre>
## S4 method for signature 'sspm_fit'
spm_time(sspm_object)
## S4 replacement method for signature 'sspm_fit'
spm_time(object) <- value</pre>
## S4 method for signature 'sspm_fit'
spm_formulas(sspm_object)
## S4 replacement method for signature 'sspm_fit'
spm_formulas(object) <- value</pre>
## S4 method for signature 'sspm_fit'
spm_smoothed_data(sspm_object)
## S4 replacement method for signature 'sspm_fit'
spm_smoothed_data(object) <- value</pre>
spm_get_fit(sspm_object)
## S4 method for signature 'sspm_fit'
spm_get_fit(sspm_object)
spm_get_fit(object) <- value</pre>
## S4 replacement method for signature 'sspm_fit'
spm_get_fit(object) <- value</pre>
## S4 method for signature 'sspm_fit'
spm_boundaries(sspm_object)
```

44 sspm

```
## S4 replacement method for signature 'sspm_fit'
spm_boundaries(object) <- value

## S4 method for signature 'sspm_fit'
spm_boundary(sspm_object)

## S4 replacement method for signature 'sspm_fit'
spm_boundary(object) <- value</pre>
```

Arguments

sspm_object [sspm_fit] An object of class sspm_fit.
object [sspm_fit] An object of class sspm_fit.

value typically an array-like R object of a similar class as x.

Value

The object in the required slot.

Examples

sspm

Create a sspm model object

Description

Create a sspm_model object.

Usage

```
sspm(biomass, predictors)

## S4 method for signature 'sspm_dataset,missing'
sspm(biomass, predictors)

## S4 method for signature 'sspm_dataset,sspm_dataset'
sspm(biomass, predictors)

## S4 method for signature 'sspm_dataset,list'
sspm(biomass, predictors)
```

sspm-class 45

Arguments

biomass [sspm_dataset (smoothed)] The dataset containing the biomass variable.

predictors [list OF sspm_dataset (smoothed)] The list of predictor datasets.

Value

An object of class sspm.

Examples

sspm-class

sspm model class

Description

The sspm model object, made from biomass, predictor and catch data.

Slots

datasets [list] List of sspm_dataset that define variables in the SPM model.

time [character] The column of data that represents the temporal dimension of the dataset.

uniqueID [character] The column of datasets that is unique for all rows of the data matrix.

boundaries [sf] Spatial boundaries (polygons).

smoothed_data [ANY (sf)] The smoothed data.

smoothed_vars [character] A vector storing the smoothed vars.

is_split [logical] Whether this object has been split into train/test sets.

46 sspm_dataset-class

Description

One of the first steps in the sspm workflow is to create one or more object(s) of class sspm_boundary from an sf object.

Slots

boundaries [sf] Spatial boundaries (polygons).

boundary [character] The column of data that represents the spatial boundaries.

boundary_area [character] The column of data that represents the area of spatial boundaries.

sspm_dataset-class

sspm dataset structure

Description

One of the first step in the sspm workflow is to create one or more object(s) of class sspm_dataset from a data.frame, tibble or sf object.

Slots

name [character] The name of the dataset, default to "Biomass".

data [data.frame OR sf OR tibble] The dataset.

biomass [character] The biomass columns of data.

density [character] The biomass density columns of data.

time [character] The column of data that represents the temporal dimension of the dataset.

coords [character] The columns of data that represent the spatial dimension of the dataset: the two columns for longitude and latitude of the observations.

uniqueID [character] The column of data that is unique for all rows of the data matrix.

boundaries [sspm_discrete_boundary] Spatial boundaries (polygons).

formulas [list] List of sspm_formula objects that specifies the smoothed variables.

smoothed_data [ANY (sf)] The smoothed data.

smoothed_vars [character] A vector storing the smoothed vars.

smoothed_fit [list] The fit from smoothing the data

is_mapped [logical] Whether the dataset has been mapped to boundaries (used internally).

sspm_discrete_boundary-class

sspm discrete boundary structure

Description

One of the first steps in the sspm workflow is to create one or more object(s) of class sspm_boundary from an sf object.

Slots

boundaries [sf] Spatial boundaries (polygons).

boundary [character] The column of data that represents the spatial boundaries.

boundary_area [character] The column of data that represents the area of spatial boundaries.

method [discretization_method] (if discrete) discretization method used.

patches [sf] (if discrete) Patches resulting from discretization.

points [sf or NULL] (if discrete) Sample points used for discretization.

patches_area [character] The column of data that represents the area of patches.

sspm_fit-class

sspm fit

Description

The fit object for a sspm model

Slots

smoothed_data [ANY (sf)] The smoothed data.

time [character] The column of smoothed_data that represents the temporal dimension of the dataset.

uniqueID [character] The column of smoothed_data that is unique for all rows of the data matrix.

formula [list] The sspm_formula object that specifies the spm model.

boundaries [sf] Spatial boundaries (polygons).

fit [bam] The fit of the spm model.

48 summary

sspm_formula-class

sspm formula object

Description

This class is a wrapper around the formula class. It is not intended for users to directly manipulate and create new objects.

Slots

```
raw_formula [formula] The raw formula call
translated_formula [formula] The translated formula call ready to be evaluated.
vars [list] List of relevant variables for the evaluation of the different smooths.
lag_vars Smooth lag variables used for predictions
response [charater] The response variable in the formula.
is_fitted [logical] Whether this formula has already been fitted.
```

See Also

See the mgcv function for defining smooths: s().

summary

Summarises sspm_fit objects

Description

Summarises a sspm_fit object, both in terms of productivity and biomass.

Usage

```
## S4 method for signature 'sspm_fit'
summary(object, biomass = NULL)
```

Arguments

object [sspm_...] An object from this package.

biomass [character] Biomass variable.

Value

Nothing is returned, but a summary is printed.

tesselate_voronoi 49

Examples

```
## Not run:
summary(sspm_model_fit)
summary(sspm_model_fit, biomass = "weight_per_km2_borealis")
## End(Not run)
```

tesselate_voronoi

Perform voronoi tesselation

Description

Generates voronoi polygons by first performing stratified sampling across boundary polygons, then by running the voronoisation with st_voronoi().

Usage

```
tesselate_voronoi(
  boundaries,
  with,
  boundary = "sfa",
  sample_surface = FALSE,
  sample_points = TRUE,
  nb_samples = NULL,
  min_size = 1500,
  stratify = TRUE,
  seed = 1
)
```

Arguments

boundaries [sf] The boundaries to be used.

with **[sf]** A set of data points to use for voronoisation.

boundary [character] The column in boundaries that is to be used for the stratified sam-

pling.

sample_surface [logical] Whether to sample the surfaces in boundaries, Default to FALSE.

sample_points [logical] Whether to sample points from with or to take all points in with.

Default to TRUE.

nb_samples [named character vector] The number of samples to draw by boundary poly-

gons (must bear the levels of boundary as names or be a single value to be

applied to each level).

min_size [numeric] The minimum size for a polygon above which it will be merged (in

km2).

stratify [logical] Whether the discretization happens within the boundaries or whether

the whole area is to be used (default to TRUE).

seed [numeric] Passed onto set.seed(), important for reproducibility of sampling.

Value

A named list with three elements (each an sf object): * patches, the voronoi polygons generated * points, the points used for the tessellation.

Examples

triangulate_delaunay

Perform delaunay triangulation

Description

Generates delaunay triangles with ct_triangulate().

Usage

```
triangulate_delaunay(
  boundaries,
  with = NULL,
  boundary = "sfa",
  sample_surface = FALSE,
  sample_points = FALSE,
  nb_samples = NULL,
  min_size = 1000,
  seed = 1,
  ...
)
```

Arguments

boundaries [sf] The boundaries to be used.

with **[sf]** A set of data points to use for voronoisation.

boundary [character] The column in boundaries that is to be used for the stratified sam-

pling.

sample_surface [logical] Whether to sample the surfaces in boundaries, Default to FALSE.

sample_points [logical] Whether to sample points from with or to take all points in with.

Default to TRUE.

nb_samples [named character vector] The number of samples to draw by boundary poly-

gons (must bear the levels of boundary as names or be a single value to be

applied to each level).

min_size

[numeric] The minimum size for a triangle above which it will be merged (in km2).

seed

[numeric] Passed onto set.seed(), important for reproducibility of sampling.

Arguments passed on to RTriangle::triangulate

- p Planar straight line graph object; see pslg.
- a Maximum triangle area. If specified, triangles cannot be larger than this area.
- q Minimum triangle angle in degrees.
- Y If TRUE prohibits the insertion of Steiner points on the mesh boundary.
- j If TRUE jettisons vertices that are not part of the final triangulation from the output.
- D If TRUE produce a conforming Delaunay triangulation. This ensures that all the triangles in the mesh are truly Delaunay, and not merely constrained Delaunay. This option invokes Ruppert's original algorithm, which splits every subsegment whose diametral circle is encroached. It usually increases the number of vertices and triangles.
- S Specifies the maximum number of added Steiner points. If set to Inf, there is no limit on the number of Steine points added but this can lead to huge amounts of memory being allocated.
- V Verbosity level. Specify higher values for more detailed information about what the Triangle library is doing.
- Q If TRUE suppresses all explanation of what the Triangle library is doing, unless an error occurs.

Value

A named list with three elements (each an sf object): * patches, the voronoi polygons generated * points, the points used for the tessellation.

Examples

\$,sspm_boundary-method

Extract methods

Description

WIP extract variables from sspm objects

Usage

```
## S4 method for signature 'sspm_boundary'
x$name

## S4 method for signature 'sspm_discrete_boundary'
x$name

## S4 method for signature 'sspm_dataset'
x$name

## S4 method for signature 'sspm'
x$name
```

Arguments

```
x [sspm_...] An object from this package.
name [character] The name of the column
```

Value

The data.frame matching the request.

Examples
